### ABSTRACT

Gentamicin (GEN) is an extensively used aminoglycoside. Contrary to its antibacterial potential, it can induce oxidative stress in several organs, including kidney. Amentoflavone (AMN) is a biflavonoid with conspicuous pharmacological activities. The current study was held to estimate the curative efficacy of AMN to antagonize the nephrotoxic effects instigated by GEN. 48 albino rats were separated into four groups: control group, GEN administrated group (80 mgkg<sup>-1</sup> intraperitoneally), GEN + AMN treated group (80 mgkg<sup>-1</sup> + 40 mgkg<sup>-1</sup>) and only AMN administrated group (40 mgkg<sup>-1</sup>). Following 30 days of administration, results showed that GEN disturbed antioxidant enzymes i.e., glutathione (GSH), glutathione reductase (GSR), glutathione peroxidase (GPx), glutathione S-transferase (GST), superoxide dismutase (SOD), catalase (CAT) activity, besides elevated malondialdehyde (MDA) along with reactive oxygen species (ROS) level. Besides this, level of inflammatory cytokines involving interleukin-6 (IL-6), nuclear factor-kappa B (NF-κB), interleukin-1 beta (IL-1β), tumor necrosis factor alpha (TNF-α) & cyclo-oxygenase-2 (COX-2) were escalated. Furthermore, treatment with GEN enhanced the level of apoptotic proteins comprising of Bax, caspase-9 along with caspase-3 besides lessened the level of Bcl-2. In addition to this, GEN reduced the level of albumin, creatinine clearance & augmented the level of creatinine, urea, urobilinogen, urinary protein, kidney injury molecules-1 (KIM-1), neutrophil gelatinase-associated lipocalin (NGAL) as well as instigated various histopathological damages. However, co-treated group (AMN + GEN) revoked abovementioned renal dysregulations instigated by GEN. Taken together, AMN could significantly counteract GEN-instigated nephrotoxic effects due to its antioxidant capabilities.

## 1. Introduction

Aminoglycosides are potential semisynthetic or natural antibiotics obtained from actinomycetes. They placed among the first-line medicines used clinically to treat infectious disturbance (Krause et al., 2016). Gentamicin (GEN) is an amino-glycosidic medicine which are employed to treat multiple life-threatening

bacterial ailments, especially from gram-negative bacteria (Virani et al., 2016). Nephrotoxicity can be induced by various sorts of agents through several mechanisms, causing cellular apoptosis and necrosis either by radiation or chemicals. About 20% of renal toxicity is provoked by drugs while this proportion is much higher in aged people following long-term exposure to these causative drugs. GEN-induced nephrotoxicity results due to the intensive production of ROS that eventually leads to renal dysfunction. About 90% of gentamicin is excreted unaltered from proximal convoluted tubules in the kidney, resulting structural variations in renal tissues. Chronic and higher doses of GEN causes *in-vitro* and *in-vivo* free radical generation triggering multiple life-threatening mechanisms (Bhatia et al., 2017).

Bioaccumulation of GEN in the proximal convoluted tubules (PCT) causes inflammation, damages in the mesangial cells, renal

tubular damages, enhance iron mediated lipid peroxidation and ultimately renal disruption due to receptor-mediated endocytosis (Nagai and Takano, 2004). In the kidneys, aggregation of GEN results in structural alterations such as removal of the brush borders and tubular deterioration (Sardana et al., 2015). The underlying mechanism of GEN-instigated renal toxicity is poorly known. Previous literature linked the GEN-caused renal toxicity with oxidative stress and brought down the defense system of nephron as well as elevated the risk of kidney dysfunction (Balakumar et al., 2010).

Flavonoids are characterized by their polyphenolic structural composition and are known to possess various pharmacological and biological properties (Maleki et al., 2019). Among these flavonoids, amentoflavone (AMN) stands out as a widely distributed biflavonoid. It consists of two apigenin molecules that are connected in a dimeric form and it contains six hydroxyl (OH) groups. AMN is primarily obtained from species of Selaginella, a genus of plants. It is eminent for its pharmacological abilities involving anti-senescence, anti-diabetes, anti-tumor and anti-inflammation (Yu et al., 2017). The objective of this study was to assess the therapeutic potential of AMN in mitigating the renal damage caused by GEN.

## 2. Material and methods

### 2.1. Chemicals

GEN was procured from Alexandria Pharmaceuticals, Egypt. AMN was bought from Chengdu Must Biotechnology, China.

### 2.2. Animals

Experiment was held on 60–70 days old 48 albino rats weighing 190–220 g. Rats were housed at the University of Agriculture Faisalabad (UAF). Constant temperature ( $25 \pm 2$  °C) and twelve hours of dark and light period were maintained. The selection of 12-hour dark/light photoperiod in experimental trial was predicated on its ability to maintain the circadian rhythm of organisms as it offered a balanced alteration between light and dark periods. It is a standard procedure that ensures comparability across studies while minimizing stress and disruption and closely emulates natural day length. Its implementation in experimental setups is also highly practical. Moreover, accessibility to food and water was ensured. Experiment was conducted in accordance with European Union of Animal Care and Experimentation (CEE Council 86/609) protocol.

### 2.3. Layout of experiment

4 groups of animals were made (6 rats in each). Control group received an administration of normal saline. The GEN-treated group received (80 mgkg<sup>-1</sup>) of GEN intraperitoneally. Co-treated rats were exposed with AMN (40 mgkg<sup>-1</sup>) orally & GEN (80 mgkg<sup>-1</sup>) intraperitoneally. Only AMN supplemented animals were administered with (40 mgkg<sup>-1</sup>) on daily basis during the entire period. The dosage of GEN, 80 mgkg<sup>-1</sup> was administered in accordance with the previous research of Kopple et al. (2002), while the usage of AMN at a dosage of 40 mgkg<sup>-1</sup> was employed, it was based on the experiment conducted by Alherz et al. (2022). On the 30th day of examination, rats were anesthetized with the help of ketamine (60 mgkg<sup>-1</sup>) as well as xylazine (6 mgkg<sup>-1</sup>), then decapitated & blood sample were taken for further analysis. After dissection, kidneys were separated, one of them was preserved in 10% formalin for histology and the other was collected in plastic bag and kept at –80 °C for the analysis of biochemical profile.

### 2.4. Biological analysis of antioxidants

The activity of CAT was analyzed using Aebi (1984) protocol while SOD's activity was analyzed with the techniques of Sun et al. (1988). The assessment of GPx activity was conducted by using the methodology developed by Lawrence and Burk. Ellman's, 1959 method was used for the assessment of activity of the GSH. GST activity was analyzed by Habig et al. (1974). The Carlberg and Mannervik (1975) approach was employed to assess GSR activity.

### 2.5. Analysis of ROS, MDA and H<sub>2</sub>O<sub>2</sub>

The concentration of ROS in the kidneys was evaluated using methodology by the Hayashi et al. (2007). Analysis of MDA level was carried out in-line with the process given by Ohkawa et al. (1979). The Pick & Keisari (1981) method was used to detect the concentration of H<sub>2</sub>O<sub>2</sub>.

### 2.6. Analysis of urine, serum profile

Employing standard diagnostic kits (MediScreen kit France), urea, urinary proteins, albumin, urobilinogen, creatinine and creatinine clearance levels were evaluated.

### 2.7. Analysis of KIM-1 & NGAL

NGAL & KIM-1 concentration was detected via KIM-1 Quantikine ELISA kits and NGAL Quantikine ELISA kits, respectively in compliance with the manufacturer's advice (R & D System China Co. Ltd., Changning, China).

### 2.8. Analysis of inflammatory markers

ELISA kits from Shanghai-YL-Biotech. Co. Ltd., China was applied for estimating the concentration of IL-1 $\beta$  (CSB-E08055r), NF- $\kappa$ B (CSB-E13148r) IL-6 (CSB-E04640r), TNF- $\alpha$  (CSB-E07379r) as well as COX-2 (CSB-E04640r).

### 2.9. Analysis of apoptotic markers

Utilizing ELISA kits from Cusabio Technology Llc, Houston, TX, USA. Caspase-3 (CSB-E08857r), Bax (CSB-EL002573RA), Bcl-2 (CSB-E08854r) and caspase-9 (CSB-E08863r) concentrations were analyzed.

### 2.10. Histological study of renal tissues

The right kidneys from each rat were divided longitudinally and placed in a solution (10% formalin) for about 24 h. Kidneys were encased in paraffin wax and sliced into small pieces by using microtome machine. These slices were stained with eosin following hematoxylin & analyzed using light microscope, Olympus BX51 (Imagetec Pvt. Ltd., Chennai, India), for histo-pathological examination.

### 2.11. Statistical evaluation

Results were demonstrated as MEAN  $\pm$  SEM. One-way ANOVA following Tukey's test was employed for comparison between treated animals.  $P < 0.05$  was set as a level of significance. Minitab (software) Version 21.1.0 was utilized for the accomplishment of analysis of data.

### 3. Results

#### 3.1. Effect of AMN on the activity of antioxidant enzymes

GEN-exposed rats manifested a notable ( $p < 0.05$ ) decline in anti-oxidant enzyme (GPx, GST, SOD, GSH, GSR) activity contrary to control condition animals. In the co-administered rats, GEN + AMN, resulted in a notable ( $p < 0.05$ ) improvement in the aforementioned enzyme's activity when matched with GEN-administered rats. Whereas, AMN (alone) administered animals displayed the normal level of enzymes (Table 1).

#### 3.2. Effect of AMN on the concentration of MDA, H<sub>2</sub>O<sub>2</sub> & ROS

GEN exposure exhibited a remarkable ( $p < 0.05$ ) escalation in levels of H<sub>2</sub>O<sub>2</sub>, MDA, ROS when matched with control rats. The animals with combine treatment of (GEN + AMN) expressed a notable ( $p < 0.05$ ) decrease in MDA, H<sub>2</sub>O<sub>2</sub>, & ROS concentration in contrast to rats intoxicated with GEN. AMN administration (alone) showed similar level of abovementioned markers as in the untreated animals (Table 2).

#### 3.3. Effect of AMN on urine and serum profile

Treatment with GEN instigate a substantial ( $p < 0.05$ ) elevation in concentration of urinary protein, urobilinogen, urea, serum creatinine as well a notable ( $p < 0.05$ ) reduction was noticed in creatinine clearance & albumin when matched with the control. However, co-administration of GEN + AMN represented a remarkable ( $p < 0.05$ ) decrease in the concentration of urobilinogen, urinary proteins, creatinine along with urea but a notable increase in the albumin and creatinine clearance was found in contrast to GEN administration. The treatment of AMN alone doesn't express any considerable difference when matched with the control animals (Fig. 1).

#### 3.4. Effect of AMN on the concentration of KIM-1 and NGAL

Treatment with GEN prompted a profound ( $p < 0.05$ ) rise in the KIM-1 & NGAL's level as compared to control condition animals. GEN + AMN significantly regulated the aforesaid dysregulation contrary to GEN group. AMN administration alone showed similar as in normal rats. (Table 3).

#### 3.5. Effect of AMN on the concentration of inflammatory markers

GEN supplemented rats represented remarkable ( $p < 0.05$ ) elevation in concentrations of pro-inflammatory markers (IL-6, TNF- $\alpha$ , COX-2, IL-1 $\beta$ , NF- $\kappa$ B) compared to the control, demonstrating GEN's role in potentially triggering inflammatory damage. The co-treated animals expressed a notable ( $p < 0.05$ ) reduction in pro-inflammatory markers when matched to the GEN administered rats. AMN when given (alone) displayed same results as in untreated group (Table 4).

GEN + AMN	1.74 $\pm$ 0.10 <sup>b</sup>	3.40 $\pm$ 0.18 <sup>b</sup>	1.86 $\pm$ 0.11 <sup>b</sup>
AMN	0.79 $\pm$ 0.06 <sup>c</sup>	0.72 $\pm$ 0.11 <sup>c</sup>	1.17 $\pm$ 0.08 <sup>c</sup>

Values exhibiting dissimilar letters varies notably from other groups.

#### 3.6. Effect of AMN on the level of apoptotic markers

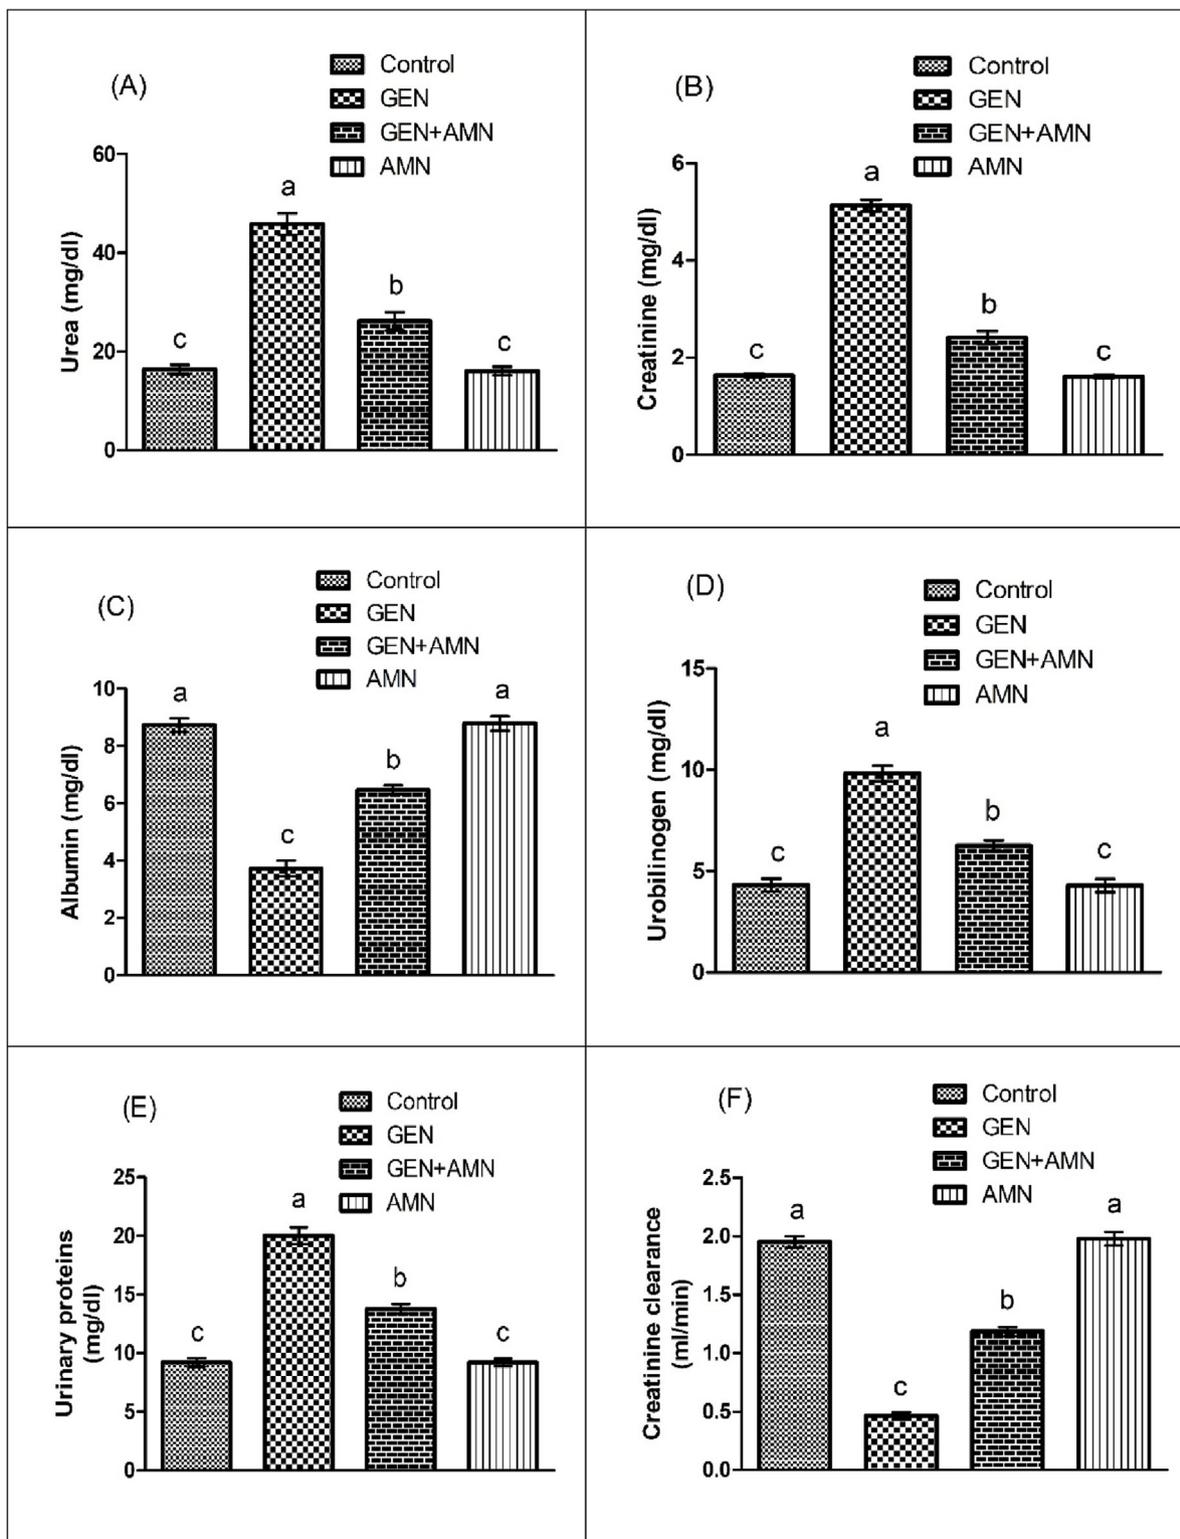

Concentrations of caspase-9, caspase-3 & Bax's level were escalated in the GEN treated group while concentration of Bcl-2 was reduced in comparison to the control, confirming that GEN has the ability to cause apoptotic injuries. The co-treated (GEN + AMN) group manifested a remarkable reduction in the pro-apoptotic marker's level relative to GEN exposed group. Whereas AMN (alone) supplementation showed similar activity of aforesaid markers with control rats (Table 5).

#### 3.7. Effect of AMN on tissue histology

The histopathological observation of the control and AMN group demonstrated the presence of a normal and intact structure of glomerulus, Bowman's capsule and convoluted tubules (Fig. 2A and D). In contrast, the glomeruli of rats treated with GEN exhibited significant congestion, accompanied by pronounced damage to Bowman's capsule & alterations in the tubular system of the kidney (Fig. 1B). However, the histopathological analysis of the co-treated group (GEN + AMN) revealed an improved morphology of the glomerular structure and restoration of the normal lining of tubular renal epithelium (Fig. 2C).

### 4. Discussion

In the present experiment, GEN administration resulted in reduction in the antioxidant enzyme's activity involving GSH, SOD, GPx, CAT, GST and GSR (Bansal et al., 2005). CAT performs a pivotal function in the substantial conversion of H<sub>2</sub>O<sub>2</sub> into H<sub>2</sub>O and molecular oxygen, consequently, it offers cellular defense against oxidative injury caused by H<sub>2</sub>O<sub>2</sub> and hydroxide ions (Aitken and Roman, 2008). SOD functions as a crucial catalyst in the transformation of superoxide anion into H<sub>2</sub>O<sub>2</sub> & oxygen (Liochev and Fridovich, 2010). GSR mediated the oxidation of glutathione disulfide, thereby altering it into its reduced form (GSH) (Kaneko et al., 2002). GSH exhibits its protective effects against oxidative stress in mammalian cells via reducing the levels of not only hydrogen peroxide but also other peroxides (Deponte, 2013). GST, being a versatile enzyme, participate in a wide range of detoxification processes via catalytically conjugating electrophilic toxins with the abundant glutathione molecules it contains (Tirmenstein and Reed, 1989). GEN administration induced a remarkable escalation in lipid peroxidation (MDA), H<sub>2</sub>O<sub>2</sub> & ROS production. Lipid peroxidation along with oxidative stress (OS)

**Fig. 1.** Effect of GEN and AMN on (A) Urea, (B) Creatinine, (C) Albumin, (D) Urobilinogen, (E) Urinary Protein, (F) Creatinine Clearance Levels. Bars Represent Mean ± SEM Values. Different superscripts on bars indicate significant differences at  $p < 0.05$ .

reduces the ability of proximal convoluted tubules to function properly which eventually results in renal failure (Ishtiaq et al., 2022; Al-Kuraishy and Al-Gareeb, 2016). The aforementioned antioxidant enzymes play a remarkable task in decreasing oxidative stress prompted deformities (Zia-Ul-Haq, 2021). CAT predominantly alters  $H_2O_2$  into  $H_2O$  (Aitken and Roman, 2008). Toxic

superoxide is primarily converted by SOD into  $H_2O_2$  and  $^1O_2$  (El-Boshy et al., 2019). GPX acts as a quencher of  $H_2O_2$  (Ballatori et al., 2009). In the present research, co-treatment GEN + AMN enhanced the activity of the above-mentioned antioxidants and diminish  $H_2O_2$ , ROS & MDA concentrations, indicating the curative action of AMN against GEN. Thus, the ability of AMN in mitigating

**Table 3**  
Effect of AMN on the concentration of KIM-1 and NGAL.

Groups	KIM-1 (ng/day)	NGAL (mg/ml)
Control	0.27 ± 0.03 <sup>c</sup>	0.60 ± 0.05 <sup>c</sup>
GEN	0.86 ± 0.05 <sup>a</sup>	1.82 ± 0.14 <sup>a</sup>
GEN + AMN	0.52 ± 0.05 <sup>b</sup>	1.13 ± 0.10 <sup>b</sup>
AMN	0.25 ± 0.04 <sup>c</sup>	0.59 ± 0.06 <sup>c</sup>

Values exhibiting dissimilar letters varies notably from other groups.

the GEN instigated oxidative disturbance in kidneys is attributed to its radicle scavenging ability as determined by invitro analysis from Bajpai et al. (2019).

Administration of GEN enhanced the concentration of renal pro-inflammatory proteins viz. IL-1β, TNF-α, IL-6 along with NF-κB which are involved in acute inflammatory responses and other severe infections correlated with escalated level of ROS (Widowati et al., 2022). Intensive upregulation of these cytokines specifically NF-κB alters renal cellular configuration, causing damage to glomerulus, proximal convoluted and distal convoluted tubules, including collecting duct, affecting rate of filtration and reabsorption which disturbs normal activity of nephron (Irkin and Öztürk, 2022; Akbaribazm et al., 2021). Our findings demonstrated that the co-treatment with AMN and GEN significantly reduced the concentration of pro-inflammatory markers. Whereas, AMN exerts therapeutic action against elevated level of above-mentioned pro-inflammatory cytokines due to its anti-inflammatory action (Kim et al., 1998).

Administration of GEN elevated the concentration of apoptotic proteins such as caspase-3, Bax & caspase-9 although down-regulated the concentration of anti-apoptotic protein Bcl-2 in rats which is related with acute apoptotic responses (Kandeil et al., 2018). This imbalance in Bcl-2 & Bax stimulate the secretion of cytochrome complex from the inner membrane of mitochondria & enhances production of caspase-3 which is a major protein that induces process of apoptosis in kidneys (Berens and Tyler, 2011). Furthermore, our findings showed that co-treatment with AMN + GEN maintained the level of pro-apoptotic markers while upregulating the concentration of Bcl-2. AMN attenuated the GEN instigated apoptotic impairments that may be attributed to its anti-apoptotic nature (Zhang et al., 2015).

In the present experiment GEN treatment instigated a considerable escalation in the creatinine, urea, urinary proteins and urobilinogen whereas we found a remarkable decrease in creatinine clearance and albumin. Besides this, concentration of KIM-1 &

**Table 4**  
Effect of AMN on the concentration of inflammatory markers.

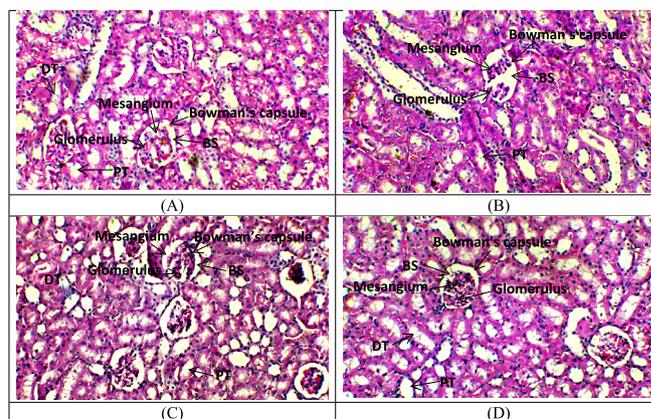

Groups	NF-κB (ng/g tissue)	TNF-α (ng/g tissue)	IL-1β (ng/g tissue)	IL-6 (ng/g tissue)	COX-2 (ng/g tissue)

**Fig. 2.** Effect of GEN and amentoflavone on renal cortex of the rats. (A) Control group presenting normal distal convoluted tubules, renal glomerulus and Bowman's space, (B) GEN treated group displaying epithelial flattening in tubules with vacuolar degeneration, atrophied glomeruli and widening of Bowman's spaces, (C) Co-treated group of GEN + AMN representing recovering distal convoluted tubules, renal glomerulus and Bowman's space almost near to normal architecture, (D) Only AMN treated group with normal glomerulus.

NGAL were also escalated substantially which are the major indicators of renal failure (Lei et al., 2015). Variation in glomerular architecture, dysregulation of filtration rate and subsequent disruption in the functions of nephron are all associated with elevated the level of nitrogenous end products (urea & creatinine) (Alvi et al., 2022; Laurent et al., 1990). Aforementioned dysregulations in the concentrations of NGAL & KIM-1 resulted in lethal conditions such as vascular damage along with proximal tubular dysfunctions (Dobrek et al., 2016). It was found that co-administration of AMN and GEN effectively downregulated the urobilinogen, urinary proteins, creatinine NGAL & KIM-1 concentrations. Besides this, the concentration of creatinine clearance & albumin was escalated. This mitigative effect may be ascribed to Reno-protective role of AMN.

In the present investigation, GEN instigated histopathological alterations including apoptotic, degradation of the epithelium in the renal tubules and contraction of glomerular mesangial cells (Lopez-Novoa et al., 2011). According to Quiros et al. (2011), GEN aggregates over a prolonged period of time in the collecting tubule's epithelial cells, resulting in intracellular alterations that eventually cause necrosis of the brush border and tubular cells. GEN instigated nephrotoxicity causes reduction in renal blood flow

through vasoconstriction, blockage of vasodilators and promotion of leukocyte marginalization (Samiee-Zafarghandy and van den Anker, 2013). Our result manifested that when AMN was given to rats in combination with GEN, overt therapeutic response was observed in the aforesaid renal damages generated by GEN. Therefore, histoprotective potential could be ascribed to its anti-apoptotic, anti-oxidant & anti-inflammatory nature of AMN.

## 5. Conclusion

The evidences from the present investigation illustrate that AMN possesses the ability to mitigate the detrimental nephrotoxic effects induced by GEN via modulating the levels of antioxidant enzymes. AMN supplementation was observed to significantly reduce renal reactive oxygen species, lipid peroxidation, serum urea and creatinine concentration. Furthermore, it demonstrated the capacity of AMN to restore the elevated levels of pro-inflammatory & pro-apoptotic markers as well as alleviate the disruption in renal tissues. These results provide evidence that AMN exhibits defensive properties that can be assigned to its anti-apoptotic, anti-oxidant, anti-inflammatory & nephroprotective capabilities.
