ABSTRACT

This experiment aimed to determine how pomegranate juice (PJ) responds to oxidative stress induced by aluminum in male mice. A total of thirty-six male mice were separated into six groups. The first group (control group) received tap water. Groups two and three were given 20% and 40% PJ, respectively. Group four received 400 mg Al/kg, while groups five and six were given Al + 20% PJ and Al + 40% PJ, respectively. After the oral administration period, the sexual behavior of the mice was recorded. Blood was collected from the heart to measure testosterone concentration. After the animals were sacrificed, the reproductive organs were weighed, and the epididymis and testis were used for further evaluations. Our findings showed that Al decreased the body and organs weights, sexual behavior, sperm count, normal sperm, total and progressive sperm motility, testosterone level, and epithelial diameters of the seminiferous tubes. In addition, the PJ reduced these effects and minimized the aluminum toxicity in male mice. In conclusion, PJ protects against aluminum exposure in male mice by ameliorating sexual behavior and fertility.

1. Introduction

Aluminum (Al) is the third most widely distributed element (8%) in the earth's crust after oxygen and silicon (Willhite et al., 2014). Aluminum has chemical and physical properties and is widely used in industry, especially the food and beverage industry (Al-Dhabi et al., 2015; Barathikannan et al., 2016; Cuong et al., 2017). Al is added to numerous commercial foods, used in the purification of drinking water and used in therapeutic treatments (Fernandez-Lorenzo et al., 1999; Scancar & Milacic 2006; Malekizadeh & Schenk 2017; Elango et al., 2017, Elango et al., 2016). The element may enter the bodies of organisms in various ways, including through the respiratory system and skin; however, the digestive system remains the primary source of entry into the human body (Fowsiya et al., 2016; Glorybai et al., 2015; Haritha

et al., 2016). Aluminum accumulation in body organs, such as those of the central nervous system, due to direct exposure causes neurotoxicity and some morphological alterations (Virk & Eslick 2015; Wang et al., 2016; Kuznetsova et al., 2017). Moreover, exposure to Al during pregnancy and lactation can affect brain development in mouse offspring (Abu-Taweel et al., 2012). In addition, Al causes male sexual dysfunction, decreased sperm concentration and motility, and increased oxidative stress in the testis (Yousef et al., 2005; Guo et al., 2009; Abu-Taweel et al., 2011; Klein et al., 2014; Martinez et al., 2017; Helan et al., 2016; Ilavenil et al., 2017). Furthermore, Al has detrimental effects on male rat fertility at low and high doses (Mouro et al., 2018).

Many antioxidant substances, such as folic acid, propolis, zinc sulphate, vitamin E, citric acid, taurine, ascorbic acid, ginger and black seed, have shown protective effects in mice, rats and rabbits after treatment with aluminum compounds (Mahdy & Farrag 2009; Yeh et al., 2009; Yousef & Salama 2009; Moselhy et al., 2012; Chen et al., 2014; Rawi et al., 2015; Yassa et al., 2017).

Pomegranate fruit (*Punica granatum*) has been consumed as a natural medicine, especially in the Middle East, because of its health benefits (Park et al., 2016, 2017; Al-Olayan et al., 2014; Ahmed et al., 2015; Alimoradian et al., 2017). Pomegranate fruit has marked antioxidant activity and high levels of polyphenols

compared to other fruits (Wang et al., 2004; Kaur et al., 2006; Zarfeshany et al., 2014).

Pomegranate juice (PJ) prevents the damage during spermatogenesis generated by lead (Leiva et al., 2011; Aksu et al., 2017) and carbon tetrachloride (Turk et al., 2016; Surendra et al., 2016). Reactive oxygen species (ROS) formed by Al compounds might be accountable for decreased semen quality (Yousef et al., 2005). Thus, the compounds in PJ, such as polyphenols, flavonoids, and anthocyanins, are considered strong antioxidants that scavenge ROS (Turk et al., 2008; Haber et al., 2011; Abdel Moneim & El-Khadragy 2013; Al-Olayan et al., 2014; Bouasla et al., 2016; Caliskan et al., 2016; Asgary et al., 2017; Derakhshan et al., 2018; Russo et al., 2018).

This experiment was carried out to explore the antioxidant activities of PJ on the sexual behavior, sperm quality and protective activity against aluminum exposure in male mice.

2. Materials and methods

2.1. Animals

Adult, male, SWR/J mice ($n = 36$, age = 25 days, body weight = 25–35 g) were housed in plastic cages in a room with automatic daily light cycles (12-h light/dark) and regulated temperature

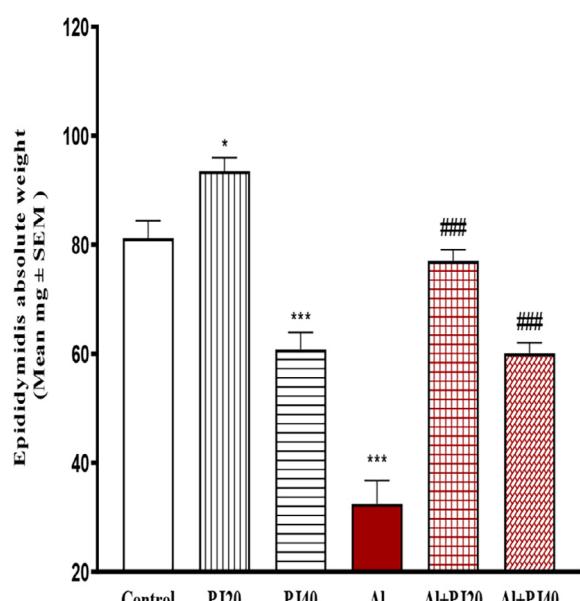

Fig. 4. Epididymis absolute weight of male mice treated with aluminum (Al), pomegranate juice (PJ) and Al + PJ.* and *** represent significant difference at ($p < 0.05$) and ($p < 0.001$) compared to control and PJ groups. ### represent significant difference at ($p < 0.001$) compared to Al group.

(22 ± 2 °C), with ideal humidity. All mice were fed a standard food and had access to tap water *ad libitum*.

2.2. Experimental design

After the animals adapted, they were separated into six groups ($n = 36$): tap water (control group), (Group I); 20% PJ (Group II); 40% PJ (Group III); 400 mg Al /kg (Group IV); 400 mg Al/kg + 20% PJ (Group V); and 400 mg Al/kg + 40% PJ (Group VI). The mice were separated in cages by group. The animals were given the various treatments orally for 35 days. One week after the last dose, blood was collected from the animal heart for testosterone hormone analysis. Then, the mice were sacrificed, and their reproductive organs were weighed. The testes and epididymis were immediately used for histological and spermatozoa evaluations. The experimental design was approved by the Institutional Review Board (IRB) of Imam Abdulrahman Bin Faisal University (IAU) (Dammam, Saudi Arabia).

2.3. Sexual behavior

The sexual behavior activities were evaluated by placing age-matched, estrous virgin females in the same cage with the experimental male mice. The sexual behavior of each male mouse was recorded for three hrs. The sexual behavior parameters (i.e., latency of copulation, frequency of copulation, duration of copulation, approach and following, threatening and biting, naso-nasal and naso-genital contacts, rears and wall rears, number of squats, number of wash and digging) were observed according to published protocols (Abu-Taweel, 2019; Park, 2011).

2.4. Sperm count, motility and morphology

The protocol used for the sperm count and motility evaluation was previously published by Oudir et al., (2018). The right epididymis was removed from the attached fat tissues. Then, the caudal epididymis was cut into small pieces in three milliliters of warmed phosphate-buffered saline (PBS) in a 35-mm petri dish and incubated (37 °C) in a water bath shaker for eight minutes. Spermatozoa concentrations were calculated using a hemocytometer. Giemsa stain was used to evaluate the abnormalities in spermatozoa from different fields of semen smears from the mice (approximately 200 sperm). Ten microliters of diluted spermatozoa were placed on a warm slide to evaluate the motility. In general, moving spermatozoa were considered motile, and other spermatozoa were counted as immotile. Spermatozoa moving in a straight line were considered progressively motile. The smears of spermatozoa in all the groups were made on warm slides, dried and stained with Giemsa. A total of 200 spermatozoa from different fields were reported as percentages of normal and abnormal, according to Li et al., (2018).

2.5. Testosterone level analysis

Blood samples were centrifuged to obtain serum and stored at -20 °C to evaluate the testosterone levels. The serum testosterone level was measured using commercial kits with some modifications.

2.6. Testicular histology

The testis were fixed in 10% formaldehyde, dehydrated and embedded in paraffin wax. The testis sections (5 µm) were stained with hematoxylin-eosin (HE) for histological assay evaluations using light microscopy (Olympus, Tokyo, Japan) at magnifications of $400 \times$ and $1000 \times$. The diameter of the seminiferous tubule

(DST) and the heights of the germinal epithelium (HGE) and lumen of seminiferous tubule (LST) were measured according to (Cordeiro et al., 2018).

2.7. Statistical analysis

The data were analyzed for normality using the Kolmogorov-Smirnov test. Then, all the parameters were analyzed (within all groups) by ANOVA post hoc testing followed by Tukey's multiple comparisons test.

3. Results

3.1. Body and reproductive organ weights

The oral administration of Al (400 mg/kg) for 35 days caused significant decreases in the body weights of the male mice compared to those in the other groups, whereas the body weight of the Al + PJ (20%) group was significantly ($p < 0.001$) higher compared to that of the Al group, especially from day 10 until day 35 (Fig. 1). The testis, seminal vesicle, epididymis and prostate weights significantly ($p < 0.001$) decreased in the Al group com-

pared to those in the other groups (Figs. 2–4). In addition, the absolute weights of these organs in the Al + PJ-treated mice were significantly higher than those of the Al-treated mice.

3.2. Sexual behavior

Al exposure led to a significant decrease ($p < 0.001$) in approach, mount, number of naso-nasal and naso-genital contacts ($p < 0.01$), following, pelvic thrust and biting ($p < 0.001$) in treated animals compared to those in the control and pomegranate juice groups (Table 1). As shown in Table 2, wall rears, rears ($p < 0.001$), and wash and digging ($p < 0.01$) were decreased, while squats were increased ($p < 0.001$) compared to those in the control and pomegranate juice groups. Tables 1 and 2 also show the benefits ($p < 0.05$, $p < 0.01$ and $p < 0.001$) of a low dose of pomegranate juice against Al toxicity.

3.3. Sperm count, sperm motility and morphology

The sperm count was significantly ($p < 0.001$) higher in animals administered 20% PJ than that in the other animals and significantly ($p < 0.05$) lower in the animals treated with Al. In addition, the male mice treated with both Al and PJ (20% or 40%) had significantly higher sperm concentrations ($p < 0.001$) than that in the mice treated with aluminum (Fig. 5).

The current findings suggested that exposure to Al caused an increase in the immotile sperm percentage, and 20% PJ decreased the negative effects of Al exposure (Fig. 6). Furthermore, PJ was

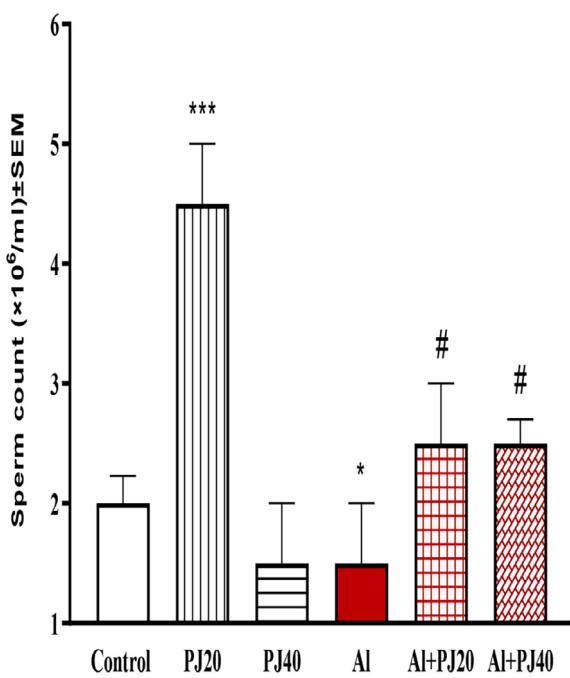

Fig. 5. Sperm count of male mice treated with aluminum (Al), pomegranate juice (PJ) and Al + PJ.motile sperm of male mice treated with aluminum (Al), pomegranate juice (PJ) and Al + PJ. *and *** represent significant difference at ($p < 0.05$) and ($p < 0.001$) respectively compared to control and PJ groups. # represent significant difference at ($p < 0.05$) compared to Al group.

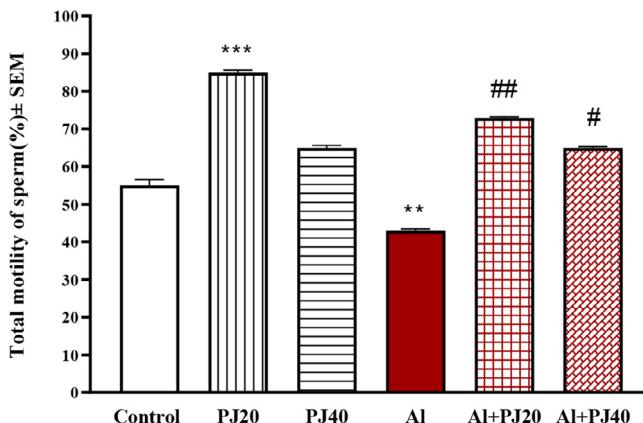

Fig. 7. Total motility of sperm of male mice treated with aluminum (Al), pomegranate juice (PJ) and Al + PJ. ** and *** represent significant difference at ($p < 0.01$) and ($p < 0.001$) respectively compared to control and PJ groups. # and ## represent significant difference at ($p < 0.01$) and ($p < 0.001$) respectively compared to Al group.

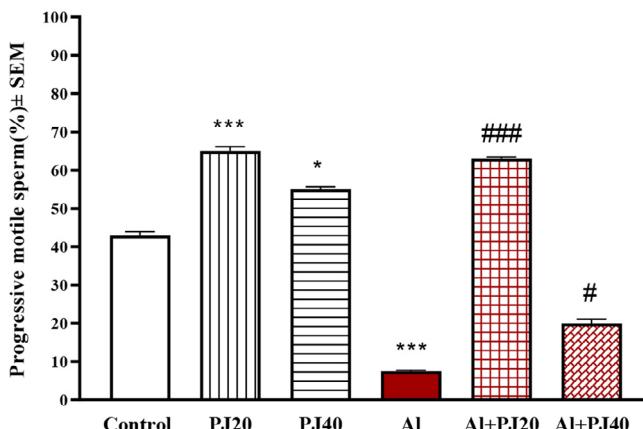

Fig. 8. The percentage of progressive motile sperm of male mice treated with aluminum (Al), pomegranate juice (PJ) and Al + PJ. * and *** represent significant difference at ($p < 0.05$) and ($p < 0.001$) respectively compared to control and PJ groups. #, ### represent significant difference at ($p < 0.05$) and ($p < 0.001$) respectively compared to Al group.

able to reduce the decline in the total and progressive motility of mouse sperm due to exposure to aluminum (Figs. 7 and 8).

There was no significant difference in the abnormal sperm in the animals that received 400 mg/kg Al compared to the animals that received tap water; however there was a strongly significant ($p < 0.0001$) increase in the percentage of abnormal sperm in the Al + 40% PJ group compared to that in the other groups (Fig. 9).

3.4. Testosterone (T) concentration in serum

The testosterone concentration was measured in blood serum at the end of experiment. The exposure to Al (400 mg/kg) led to a significant ($p < 0.001$) reduction in serum T concentration compared to that in the other groups, and PJ (20% or 40%) ameliorated this depletion in testosterone level (Fig. 10).

3.5. Testicular histological evaluations

In the Al + PJ40 group, the seminiferous tubules had a smaller diameter ($p < 0.05$) than that in the Al group (Fig. 11). In addition, there were not significant differences in the epithelial diameter of the S.T. between the groups (Fig. 12); however, there was a signif-

Fig. 9. icant increase in the lumen diameter of the S.T. in the aluminum group compared to that in the PJ20 ($p < 0.001$) and PJ40 ($p < 0.01$) groups, and PJ decreased this effect, as shown in the figures (Figs. 13 and 14).

4. Discussion

This study demonstrated the toxicity of aluminum through its effects on the body and reproductive organ weights, sperm count and motility, and testosterone concentration, and this study also

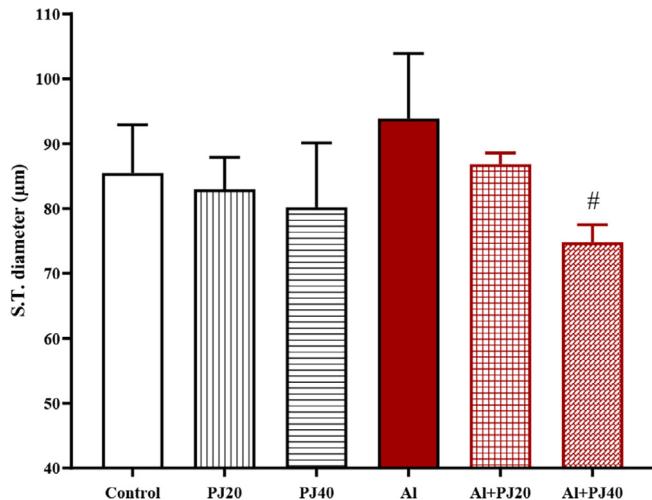

Fig. 11. Seminiferous tubes diameter of male mice treated with aluminum (Al), pomegranate (PJ) and Al + PJ.[#] represent significant difference at ($p < 0.05$) compared to Al group.

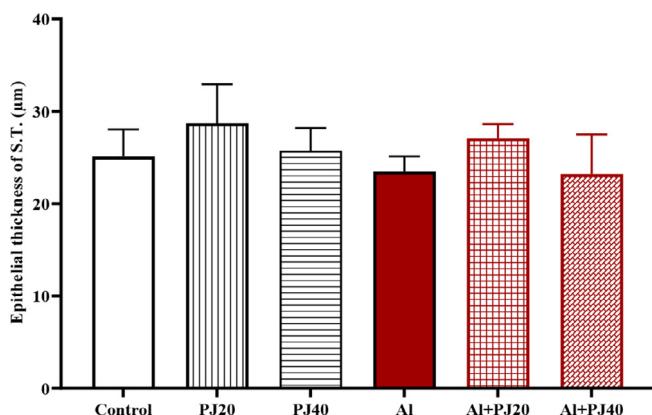

Fig. 12. Epithelial thickness of seminiferous tubes of male mice treated with aluminum (Al), pomegranate (PJ) and Al + PJ.

demonstrated the effectiveness of PJ in reducing the effects of Al. The decrease in the body and reproductive organ weights in animals treated with Al in this study is consistent with previous reports (Yousef & Salama 2009; Zhu et al., 2014; Miska-Schramm et al., 2017). These studies showed that aluminum-treated animals (i.e., mice, rats and rabbits) exhibited significantly lower body, testes, seminal vesicle and epididymis weights than the control animals. This decrease in body and organ weights may be due to mitochondrial dysfunction and glucose metabolism disruption; thus, mitochondria may be one of the possible targets of the harmful effects of aluminum (Xu et al., 2017). The combination of PJ and aluminum in this study significantly reduced the toxic effects of Al by ameliorating the reduction in the body and organ weights.

Furthermore, the current findings suggest that aluminum can reduce testosterone concentration and motility and increase abnormal spermatozoa. The effects on the testosterone level agree with previous findings in animals exposed to aluminum (Guo et al., 2001, 2005; Yousef et al., 2005; Zhu et al., 2014; Martinez et al., 2017). One study reported that aluminum suppressed T secretion in male rats, thus decreasing sperm count (Sun et al., 2011).

On the other hand, it was reported that Al increased lipid peroxidation (LP) and reduced the antioxidant defense in rat testes (Yousef & Salama 2009). Furthermore, spermatozoa were shown to be oversensitive to oxidative stress because of their limited antioxidant concentrations (Aitken 1995). In the current study, pomegranate juice exhibited a clear antioxidant effect to mitigate the disruption in the testes, especially by maintaining the testosterone concentration and sperm count and quality. Aksu et al., (2017) suggested that the protective effect of pomegranate against Pb toxicity was stronger in the testes compared to that in other organs in male rats.

Our data suggested that the sexual behavior of male mice, such as approach, contact, following, pelvic thrusting and biting, are negatively affected by exposure to aluminum. These deleterious effects may be attributed to the decrease in the concentration of testosterone, which is responsible for sexual behavior. The relationship between the synthesis of T and the sexual behavior of male mice was proven in a previous study (Zang et al., 2016). In addition, PJ improved the impairments in sexual behavior after exposure to Al. It has been well-established that testes function and sexual behavior are controlled by the hypothalamic-pituitary-gonadal axis (HPGA). Sexual behavior may be affected by T

Fig. 13. Fig. 14. Histological sections of S.T. of mice testis in different groups in this study. * refers to increasing in lumen diameter of S. T. in Al group. Scale bar = 10 μ m.

levels in Leydig cells, which, in turn, impacts dopamine secretion from the hypothalamus (Sharma et al., 2011). Additionally, the increase in the stress hormone cortisol can decrease gonadotropin-releasing hormone (GnRH) and, therefore, decrease the LH and FSH hormones, which control the T levels and spermatogenesis (Collodel et al., 2008). Oxidative stress can interrupt endocrine function and inhibit T production (Wang et al., 2017). Previous studies reported that PJ benefited antioxidant activity effects and metal detoxification, reducing stress and ameliorating sexual behavior in male rats (Hong et al., 2008; Turk et al., 2008; Dkhil et al., 2013; Aksu et al., 2017; Lydia et al., 2019).

In conclusion, this study demonstrated the toxicity of aluminum by its effects on animal body and organ weights, sperm count, sperm motility and testosterone concentration in male mice; however, PJ exhibits protective activity against these effects by ameliorating sexual behavior and fertility.
